1 | **When is it possible to transform the coefficient matrix into the identity matrix?**

When the matrix is square and has an inverse.

2 | **What should RREF be?**

If we are trying to get "as close as possible" to the identity, then we should prioritize the top left corner. So, for a non-square matrix RREF is the matrix where the top or left square is the identity matrix and everything else is zero, or failing the zeros everything else is as many zeros as possible, or failing that just anything. If the top/left square cannot be the identity matrix, then fill in as large an identity matrix as possible.
