# 1 | Virus Infections and Lifecycle

## 1.1 | Viral Life Cycle, an Overview

1. **Attachment** => protein contact between virus and host
2. **Viral entry/Uncoating** => shedding the protein layer
3. **Biosynthesis** => make baby viruses
  1. **Genome Replication:** transcribe DNA/RNA
  2. **Genome Expression:** read DNA/RNA to make proteins
4. **Viral genome integration** => retrovirus only
5. **Assembly** => put it all together
6. **Viral Exit** => mature virions leave

### **Viral Entry** *Option 1: Direct Injection/insertion*

- Insert genome through the bi-layer
- Leave the rest behind
- Tada!

### *Option 2: Endocytosis*

- Trick the host cell into introducing the virus as food
- Endocytosis!
- Bam

### *Option 3: Fusion*

- Virus fuse with cell membrane
- Shed the protein coat once in
- Shazam!

**All of these involve attachment first, which usually takes two steps.**

This process causes the organism-specific response to viruses:

1. **Attachment:** adhere roughly to random sugar proteins
2. **Binding:** roll over slowly, and bind to the entry receptor it needs

### **Uncoating**

- Virus triggers *early endosome*
  - Causes pH dependent protein denaturation
  - Causing the capsid to fall apart
  - Triggering *late endosome* => releasing genome

## Viral Replication Key questions:

- **How are viral mRNAs produced from the viral genome?** => virus will hijack the ribosomes in the host cells. So, it is more important to ask how the mRNAs are produced to tell ribosomes what to do
- **What serves as the template for viral genome replication** => replication will need a polymerase; but the source and mechanism is dependent on viral genome structure/composition

Figure 1: Screen Shot 2020-10-12 at 11.04.53 PM.png

## DNA Viruses

*How are viral mRNAs produced from the viral genome?*

- Viral DNA enters, through RNA polymerase II in the host cell, mRNA is produced
- mRNAs then read by ribosomes, and there we go

*What serves as the templates for viral genome replication?*

- Viral DNA serves as template for host cell DNA polymerase
- Viral genome copied repeatedly
- Virus, then, **will be replicated within the nucleus** due to it needing the polymerase to copy DNA

Except! Poxviridae carry their own polymerase, so they replicate in the cytoplasm.

## RNA Viruses

*How are viral mRNAs produced from the viral genome?*

**Packaging** Does not require ATP. Just sealed in.

## Viral Exits Lysis

Replicate so much that the membrane bursts.

## Budding

Trigger...

- Trigger exocytosis
- Meanwhile, send virus's own spikes to the membrane
- On exit by exocytosis, steal a part of the newly-spikey membrane with it to serve as new casing
