1 | Series Convergence

1.1 | Geometric Series

In $\sum_{k=0}^{\infty} a(r^k)$, where $|r| < 1$, the series converges to $\sum_{k=0}^{\infty} a(r^k) = \frac{a}{1-r}$

In $\sum_{k=0}^{n} a(r^k)$, $\sum_{k=0}^{n} a(r^k) = \frac{a-ar^{n+1}}{1-r}$

1.2 | nth term divergence test

If $\lim_{n\to\infty} a_n$ is not zero, the series **will** diverge. The inverse is not necessarily true; that is, if this fails, use another test to test convergence.

1.3 | Intergral Test

If the intergral to infinity is convergent, the sequence is convergent as long as the sequence is continuous, positive, and decreasing. The inverse applies, too.

1.4 | Power Series

$\sum_{n=1}^{\infty} \frac{1}{n^p}$

If a p-series has a p > 1, the p-series will converge

If a p-series has a p <= 1, the p-series will diverge

1.5 | Comparison Test

Pasted image 20210308082201.png

Also, if $\lim_{n\to\infty} \frac{a_n}{b_n} = C\ (0 < c < \infty)$, the two series will either both converge or both diverge. So you only need to test one.

Both provided that $a_n, b_n \geq 0\ \&\ a_n \leq b_n$

1.6 | Alternating Series Test

Pasted image 20210309081249.png

1.7 | Ratio Test

In a geometric series, the common ratio is simply $r = \frac{r^{n+1}}{r^n}$.

If r is an real value, $|r| < 1$, then series converges. If $|r| \geq 1$, the series diverges.

As limit goes to infinity in the r, if the common ratio approaches <1, that means that the ratio will get smaller and smaller, just like if r were to be a real value and it was smaller than one. Meaning that the series **converges.**

Pasted image 20210310083028.png

And so, formally.

Pasted image 20210310083142.png

The inverse is true, too.

However, if the ratio is equal to one, the test is inconclusive.

Absolute Convergence => series who converge and whose absolute value converges

Conditional Convergence => series who converge and whose absolute value does not converge
