1 | Mutation and Inheritance

1.1 | Cell Division, Cell Cycle & It's Regulation

Each cell lives and reproduced on a cycle; unsurprisingly, this is called the KBHBIO101CellLifecycle!

- These cell cycles create [KBhBIO101GeneticVariation], even in [KBhBIO101Mitosis], because yes!, in mitosis, there could be [KBhBIO101Mutations] which introduce variation
- However [KBhBI0101Mutations] could cause cancer if left unchecked, so we have [KBhBI0101CellCycleRegulation] to keep this cycle check.

At the end of the cell cycle, a little bit of a thing happens where the cell replicates (or makes off-springs, so not necessarily exact copies of) itself. This bit of a thing's called [KBhBIO101CellReproduction].

- This reproduction process uses one of either [KBhBIO101Miltosis] (exact copy, for somatic cells (not sperm/egg) only) or
- IKBHBIO101Meiosis (half, randomly-mixed genetic info, for gametes (sperm/egg) only).

1.2 | Genetics and Inheritance

[KBhBIO101GeneticVariation] is like, really good. However, its woefully complicated and there are at least 3 ways I think of that it happens.

- Connecting sequence variation at the DNA level to protein function
- · Connecting protein function to expressed traits in organisms
 - · Given an individual with two particular alleles of a gene, what trait would you expect to see.
- Connecting protein function and traits to inheritance patterns:
 - Given parents with particular alleles of genes, what would you expect in their offspring and why.
